Abstract

We have attempted to extend the parameter space of the elements of the texture 4 zero Hermitian quark mass matrices, to include the case of ‘weak hierarchy’ amongst them along with the usually considered ‘strong hierarchy’ case. This has been carried out by giving wide variation to the hierarchy defining parameters D_U and D_D , having implications for the structural features of the mass matrices. We find that not only the weakly hierarchical mass matrices are able to reproduce the strongly hierarchical mixing angles but also both the phases having their origin in the mass matrices have to be non zero to achieve compatibility of these matrices with recent quark mixing data. Further noting the difference between the exclusive and inclusive values of V_{ub} , we have carried out separate analyses corresponding to these.

1 Introduction

In the last few years, several important developments have taken place in the context of phenomenology of Cabibbo-Kobayashi-Maskawa (CKM) matrix [1], both from theoretical as well as experimental point of view. In this context, it may be noted that texture specific mass matrices seem to be very helpful in understanding the pattern of quark mixings and CP violation [2, 3]. Likewise, in the leptonic sector also texture zero mass matrices [4]-[6] have proved to be useful in explaining the pattern of neutrino masses and mixings, some of which have been recently measured with a good deal of accuracy. In particular, the Fritzsch-like texture four zero quark mass matrices are quite successful in reconciling the

strong hierarchy of quark masses and the smallness of flavor mixing angles [2, 3]. Similarly, in the case of neutrinos, the texture four zero mass matrices are able to accommodate the neutrino oscillation data representing large mixing angles quite well [4]-[6]. Further, apart from being related to the Nearest Neighbor Interaction (NNI) form of the mass matrices through weak basis rotations [7], these texture 4 zero mass matrices are known to be compatible with specific models of GUTs, e.g., SO(10) [2, 4, 8, 9] and these could be obtained using considerations of Abelian family symmetries [10]. Furthermore, in case we have to consider quark-lepton unification [11], then it becomes interesting to note that the corresponding Fritzsch-like texture 4 zero neutrino mass matrices have been shown to be seesaw invariant [12]. Also, it may be added that the structure of these matrices is very much in agreement with the hypothesis of natural mass matrices advocated by [13].

It may be mentioned that in the case of quark mass matrices, usually the elements are assumed to follow ‘strong hierarchy’, whereas there is no such compulsion for the leptonic mass matrices. Therefore, in case we have to invoke quark-lepton unification [11], it becomes interesting to examine whether ‘weakly hierarchical’ quark mass matrices are able to reproduce the mixing data which involves strongly hierarchical parameters. This is all the more important as the texture 4 zero mass matrices perhaps provide the simplest parallel structure for quark and lepton mass matrices which are compatible with the low energy data.

Realizing the importance of Fritzsch-like Hermitian texture 4 zero mass matrices in the context of quarks, as emphasized above, a few years back Xing and Zhang [14] have attempted to find the parameter space of the elements of these mass matrices. Their analysis has provided good deal of information regarding the space available to various parameters as well as have provided valuable insight into the ‘structural features’ of texture 4 zero mass matrices. In this context, it may be noted that the hierarchy of the elements of the mass matrices is largely governed by the (2,2) element of the matrix. In their analysis, attempt has been made to go somewhat beyond the minimal values of this element, corresponding to the ‘strong hierarchy’ case, however in case we have to consider the ‘weak hierarchy’ case as well then there seems a further need to consider a still larger range for this element. Further, their analysis has also given valuable clues about the phase structure of the mass matrices, in particular for the strong hierarchy case they conclude that only one of the two phase parameters plays a dominant role. Since, the phases of the mass matrices play a crucial role in giving information about the CP violating phase of the CKM matrix, therefore it would be interesting to find out the ranges of both the phases in the context of strong as well as weak hierarchy of the elements of the mass matrices.

It may be noted that in the last few years there have been considerable improvements in the measurement of CKM parameters and light quark masses. However, at present, even after recent updating by various groups [15]-[18], the situation regarding the element V_{ub} is not as clear as for the other CKM matrix elements. For example, as per PDG 2008 [15] its exclusive and inclusive values respectively are $(3.5^{+0.6}_{-0.5})10^{-3}$ and $(4.12 \pm 0.43)10^{-3}$. It may be noted that although the difference between the exclusive and inclusive values of V_{ub} is not statistically significant, however recent unitarity based analyses [19, 20] as well

as results from a global fit [16] emphasize exclusive value of V_{ub} . Therefore, it becomes important to examine separately the implications of exclusive and inclusive values of V_{ub} for the phenomenology of quark mass matrices.

The purpose of the present work is to update and broaden the scope of the analysis carried out by Xing and Zhang [14] as well as to examine the implications of recent precision measurements on the structural features of texture 4 zero mass matrices for exclusive and inclusive V_{ub} separately. Taking clue from the quark-lepton symmetry it would also be desirable to explore the parameter space of the elements of the mass matrices, considering not only the usual ‘strong hierarchy’ amongst them but also for the ‘weak hierarchy’ case. In view of the more precise information regarding CP violating parameters, it would be interesting to find out the ranges of both the phases having their origin in the mass matrices which are compatible with the quark mixing data. Further, for the sake of completeness it would also be desirable to construct the CKM mixing matrix as well as to evaluate the Jarlskog’s rephasing invariant parameter J and the CP violating phase δ .

The detailed plan of the paper is as follows. In Section (2), we detail the essentials of the formalism regarding the texture specific mass matrices. Inputs used in the present analysis and the methodology of the calculations have been given in Section (3). The discussion of the results have been presented in Section (4). Finally, Section (5) summarizes our conclusions.

2 Formalism

To begin with, we define the modified Fritzsch-like matrices, e.g.,

$$M_i = \begin{pmatrix} 0 & A_i & 0 \\ A_i^* & D_i & B_i \\ 0 & B_i^* & C_i \end{pmatrix}, \quad i = U, D, \quad (1)$$

M_U and M_D , respectively corresponding to the mass matrix in the up sector and the down sector. It may be noted that each of the above matrix is texture 2 zero type with $A_i = |A_i|e^{i\alpha_i}$ and $B_i = |B_i|e^{i\beta_i}$. The various relations between the elements of the mass matrices A_i, B_i, C_i, D_i essentially correspond to the structural features of the mass matrices including their hierarchies.

In the absence of any standard definition in the literature for ‘weak’ and ‘strong’ hierarchy of the elements of the mass matrices, for the purpose of present work we consider these as follows. As is usual the element $|A_i|$ takes a value much smaller than the other three elements of the mass matrix which can assume different relations amongst each other, defining different hierarchies. For example, in case $D_i < |B_i| < C_i$ it would lead to a strongly hierarchical mass matrix whereas a weaker hierarchy of the mass matrix implies $D_i \lesssim |B_i| \lesssim C_i$. It may also be added that for the purpose of numerical work, one can conveniently take the ratio $D_i/C_i \sim 0.01$ characterizing strong hierarchy whereas $D_i/C_i \gtrsim 0.2$ implying weak hierarchy. This can be understood by expressing these parameters in terms of the quark masses, in particular $D_U/C_U \sim 0.01$ implies $C_U \sim m_t$ and $D_D/C_D \sim$

0.01 leads to $C_D \sim m_b$.

To facilitate diagonalization, the complex mass matrix M_i ($i = U, D$) can be expressed as

$$M_i = Q_i M_i^r P_i \quad (2)$$

or

$$M_i^r = Q_i^\dagger M_i P_i^\dagger, \quad (3)$$

where M_i^r is a real symmetric matrix with real eigenvalues and Q_i and P_i are diagonal phase matrices. The matrix M_i^r can be diagonalized by the orthogonal transformation, e.g.,

$$M_i^{\text{diag}} = O_i^T M_i^r O_i, \quad (4)$$

where

$$M_i^{\text{diag}} = \text{diag}(m_1, -m_2, m_3), \quad (5)$$

the subscripts 1, 2 and 3 referring respectively to u, c and t for the U sector as well as d, s and b for the D sector. Using the invariants, $\text{tr} M_i^r$, $\text{tr} M_i^{r^2}$ and $\det M_i^r$, the values of the elements of the mass matrices A_i , B_i and C_i , in terms of the free parameter D_i and the quark masses are given as

$$C_i = (m_1 - m_2 + m_3 - D_i), \quad (6)$$

$$|A_i| = (m_1 m_2 m_3 / C_i)^{1/2}, \quad (7)$$

$$|B_i| = [(m_3 - m_2 - D_i)(m_3 + m_1 - D_i)(m_2 - m_1 + D_i) / C_i]^{1/2}. \quad (8)$$

The exact diagonalizing transformation O_i is expressed as

$$O_i = \begin{pmatrix} \pm \sqrt{\frac{m_2 m_3 (C_i - m_1)}{(m_3 - m_1)(m_2 + m_1) C_i}} & \pm \sqrt{\frac{m_1 m_3 (C_i + m_2)}{C_i (m_2 + m_1)(m_3 + m_2)}} & \pm \sqrt{\frac{m_1 m_2 (m_3 - C_i)}{C_i (m_3 + m_2)(m_3 - m_1)}} \\ \pm \sqrt{\frac{m_1 (C_i - m_1)}{(m_3 - m_1)(m_2 + m_1)}} & \mp \sqrt{\frac{m_2 (C_i + m_2)}{(m_3 + m_2)(m_2 + m_1)}} & \pm \sqrt{\frac{m_3 (m_3 - C_i)}{(m_3 + m_2)(m_3 - m_1)}} \\ \mp \sqrt{\frac{m_1 (m_3 - C_i)(C_i + m_2)}{C_i (m_3 - m_1)(m_2 + m_1)}} & \pm \sqrt{\frac{m_2 (C_i - m_1)(m_3 - C_i)}{C_i (m_3 + m_2)(m_2 + m_1)}} & \pm \sqrt{\frac{m_3 (C_i - m_1)(C_i + m_2)}{C_i (m_3 + m_2)(m_3 - m_1)}} \end{pmatrix}. \quad (9)$$

It may be noted that while finding the diagonalizing transformation O_i , one has the freedom to choose several equivalent possibilities of phases. Similarly, while normalizing the diagonalized matrix to quark masses, one again has the freedom to choose the phases for the quark masses. This is due to the fact that the diagonalizing transformations of M_U and M_D occur in a particular manner in the weak charge current interactions of quarks to give the CKM mixing matrix. As is usual, we have chosen the phase of m_2 to be negative facilitating the diagonalization process as well as the construction of the CKM matrix. This is one of the possibilities considered by Xing and Zhang [14], in particular it corresponds to their $(\eta_u, \eta_d) = (-1, -1)$. The other possibilities considered by them are related and are all equivalent as well, these only redefine the phases ϕ_1 and ϕ_2 which in

any case are arbitrary. For the present work, we have chosen the possibility,

$$O_i = \begin{pmatrix} O_i(11) & O_i(12) & O_i(13) \\ O_i(21) & -O_i(22) & O_i(23) \\ -O_i(31) & O_i(32) & O_i(33) \end{pmatrix}. \quad (10)$$

The CKM mixing matrix V_{CKM} which measures the non-trivial mismatch between diagonalizations of M_U and M_D can be obtained using $O_{U(D)}$ through the relation

$$V_{\text{CKM}} = O_U^T (P_U P_D^\dagger) O_D. \quad (11)$$

Explicitly, the elements of the CKM mixing matrix can be expressed as

$$V_{lm} = O_{1l}^U O_{1m}^D e^{-i\phi_1} + O_{2l}^U O_{2m}^D + O_{3l}^U O_{3m}^D e^{i\phi_2}, \quad (12)$$

where the subscripts l and m run respectively over u, c, t and d, s, b with $\phi_1 = \alpha_U - \alpha_D$, $\phi_2 = \beta_U - \beta_D$.

3 Inputs used and calculations

Before discussing the results of our analysis, we would first like to briefly mention the inputs used for carrying out the calculations. We have adopted the following ranges of quark masses [21] at the M_z energy scale, e.g.,

$$\begin{aligned} m_u &= 1.27_{-0.42}^{+0.5} \text{ MeV}, & m_d &= 2.90_{-1.19}^{+1.24} \text{ MeV}, & m_s &= 55_{-15}^{+16} \text{ MeV}, \\ m_c &= 0.619 \pm 0.084 \text{ GeV}, & m_b &= 2.89 \pm 0.09 \text{ GeV}, & m_t &= 171.7 \pm 3.0 \text{ GeV}. \end{aligned} \quad (13)$$

The light quark masses m_u , m_d and m_s have been further constrained using the following mass ratios given by [22]

$$m_u/m_d = 0.553 \pm 0.043, \quad m_s/m_d = 18.9 \pm 0.8. \quad (14)$$

Further, we have given full variation to the phases ϕ_1 and ϕ_2 , the parameters D_U and D_D have been given wide variation in conformity with the hierarchy of the elements of the mass matrices e.g., $D_i < C_i$ for $i = U, D$. The extended range of these parameters allows one to carry out the calculations for the case of weak hierarchy of the elements of the mass matrices as well. Also, it needs to be mentioned that the present range of D_U and D_D is much wider than the one considered by Xing and Zhang [14]. In particular, we have considered $D_i/C_i \sim 0.05 - 0.8$, whereas Xing and Zhang have emphasized $D_i/C_i \sim 0.1$ which corresponds to the case of strong hierarchy amongst the elements of the mass matrices. Furthermore, we have imposed the following constraints due to the latest PDG 2008 values [15],

$$|V_{us}| = 0.2255 \pm 0.0019, \quad |V_{cb}| = (41.2 \pm 1.1)10^{-3},$$

$$\begin{aligned}
V_{ub}(\text{excl.}) &= 0.0035 \pm 0.0006, & V_{ub}(\text{incl.}) &= 0.00412 \pm 0.00036, \\
\sin 2\beta &= 0.681 \pm 0.025.
\end{aligned}
\tag{15}$$

It may be noted that the calculations have been carried out separately for both exclusive and inclusive values of $|V_{ub}|$.

4 Results and discussion

In view of the fact that one of the aim of the present analysis is to update as well as to extend the analysis of Xing and Zhang [14], for exclusive and inclusive value of $|V_{ub}|$ we have carried out a detailed analysis regarding the structural features of the mass matrices by incorporating the extended ranges of the elements D_i ($i = U, D$) as well as by imposing the constraints given in equation (15). To this end, we first present the results pertaining to exclusive value of $|V_{ub}|$, the case of its inclusive value will be discussed later.

To begin with, in figure 1 we have plotted C_U/m_t versus C_D/m_b . A look at the figure reveals that both C_U/m_t as well as C_D/m_b take values from $\sim 0.55 - 0.95$, which interestingly indicates the ratios being almost proportional. Also, the figure gives interesting clues regarding the role of strong and weak hierarchy. In particular, one finds that in case one restricts to the assumption of strong hierarchy then these ratios take large values around 0.95. However, for the case of weak hierarchy, the ratios C_U/m_t and C_D/m_b take much larger number of values, in fact almost the entire range mentioned above, which are compatible with the data.

In figure 2, the plot of D_U/B_U versus D_D/B_D has been given which clearly brings out that the ratio $D_U/B_U \sim 0.2 - 0.95$ whereas the ratio $D_D/B_D \sim 0.15 - 0.9$. One finds that when the strong hierarchy assumption is considered then the ratio D_U/B_U takes value around 0.25 whereas $D_D/B_D \sim 0.2$. Again, we find that the ranges of these ratios corresponding to the weak hierarchy cases are much wider. The ranges of the parameters plotted in figures 1 and 2 not only have implications for the structural features of the mass matrices, but also indicate that there are large number of possibilities for which one can achieve compatibility of texture 4 zero mass matrices with the CKM mixing data.

In figure 3, we present the plot of ϕ_1 versus ϕ_2 . Interestingly, the present refined inputs limit the ranges of the two phases to $\phi_1 \sim 76^\circ - 92^\circ$ and $\phi_2 \sim 1^\circ - 11^\circ$. Keeping in mind that full variation has been given to the free parameters D_U and D_D , corresponding to both strong as well as weak hierarchy cases, it may be noted that the allowed ranges of the two phases come out to be rather narrow. In particular, for the strong hierarchy case one gets $\phi_2 \sim 10^\circ$, whereas for the case of weak hierarchy ϕ_2 takes almost its entire range mentioned above. Further, it may be mentioned that this figure should not be directly compared with the corresponding ϕ_1 versus ϕ_2 plot given by [14] as they have considered different initial phases. Also, our analysis indicates that although $\phi_1 \gg \phi_2$, still both the phases are required for fitting the mixing data. It may also be noted that the phases ϕ_1 and ϕ_2 and the elements of the CKM mixing matrix can be easily used to obtain angles of the unitarity triangle.

It may be noted that a comparison of these figures with the corresponding plots by [14] immediately reveals that in the specified ranges of the parameters our results are compatible with theirs. Further, it may be noted that a direct comparison of the ranges of various parameters considered by us and those given by [14] is not possible, however one may be able to compare the ranges of the elements of the mass matrices, which will be discussed later. For the other figures given in their analysis, it may be mentioned that we obtain the ones which are quite compatible with their plots as well as lead to similar consequences and so these are not presented here.

As a next step, we would like to emphasize the role of the hierarchy defining parameters D_U and D_D . To this end, in figure 4 we have plotted D_U/m_t versus D_D/m_b , representing an extended range of the parameters D_U and D_D . A closer look at the figure reveals both D_U/m_t as well as D_D/m_b take values $\sim 0.05 - 0.5$. The lower limit of the range i.e. when the ratios D_U/m_t and D_D/m_b are around 0.05 corresponds to strong hierarchy amongst the elements of the mass matrices, whereas when the elements have weak hierarchy then these ratios take a much larger range of values. From this one may conclude that in the case of strongly hierarchical elements of the texture 4 zero mass matrices, we have limited compatibility of these matrices with the quark mixing data, whereas the weakly hierarchical ones indicate the compatibility for much broader range of the elements.

The above discussion can also be understood by the construction of the mass matrices. However, as the phases of the elements of the mass matrices can be separated out, as can be seen from equation (3), one needs to consider M_i^r ($i = U, D$) instead of M_i . The ranges of the elements of these matrices M_U^r and M_D^r are as follows

$$M_U^r = m_t \begin{pmatrix} 0 & 0.000174 - 0.000252 & 0 \\ 0.000174 - 0.000252 & 0.0464 - 0.4870 & 0.2184 - 0.5017 \\ 0 & 0.2184 - 0.5017 & 0.5094 - 0.9500 \end{pmatrix}, \quad (16)$$

$$M_D^r = m_b \begin{pmatrix} 0 & 0.003555 - 0.006154 & 0 \\ 0.003555 - 0.006154 & 0.0276 - 0.4448 & 0.2194 - 0.5044 \\ 0 & 0.2194 - 0.5044 & 0.5418 - 0.9505 \end{pmatrix}. \quad (17)$$

These matrices lead to interesting consequences regarding the structural features characterized by relative magnitudes of the elements of the mass matrices. It may be noted that the elements of the mass matrices A_i , B_i , C_i and D_i satisfy the relation $|B_i|^2 - C_i D_i \simeq m_2 m_3$ for both the strong and the weak hierarchy cases characterized respectively by $D_i < |B_i| < C_i$ and $D_i \lesssim |B_i| \lesssim C_i$. This relation can be easily derived by using expressions mentioned in equation (8) as well as can be numerically checked from the above mentioned mass matrices in equations (16) and (17). The above constraint on the elements of the mass matrices as well as the ranges of various ratios, particularly in the case of weak hierarchy, provide an interesting possibility for checking the viability of various mass matrices formulated at the GUTs scale or obtained using horizontal symmetries. From a different point of view, this can also provide vital clues to the formulation of mass

matrices which are in agreement with the low energy data.

Coming to the results pertaining to the inclusive value of V_{ub} , we find that the corresponding figures do not show much change as compared to the earlier figures plotted using the exclusive value of V_{ub} , therefore these have not been presented here. The mass matrices M_U^r and M_D^r constructed using the inclusive value of V_{ub} are as follows

$$M_U^r = m_t \begin{pmatrix} 0 & 0.000179 - 0.000266 & 0 \\ 0.000179 - 0.000266 & 0.0696 - 0.4928 & 0.2610 - 0.5018 \\ 0 & 0.2610 - 0.5018 & 0.5036 - 0.9268 \end{pmatrix}, \quad (18)$$

$$M_D^r = m_b \begin{pmatrix} 0 & 0.003303 - 0.006462 & 0 \\ 0.003703 - 0.006462 & 0.0552 - 0.4586 & 0.2686 - 0.5065 \\ 0 & 0.2686 - 0.5065 & 0.5280 - 0.9236 \end{pmatrix}. \quad (19)$$

A comparison of these matrices with the ones mentioned in equations (16) and (17) reveals that the (2,2) element D_i of these matrices appear to be quite different for the corresponding M_U^r and M_D^r matrices for the case of exclusive and inclusive values of V_{ub} . Similarly, the lower limits of the element B_i of the mass matrices are quite different for both the M_U^r and M_D^r matrices corresponding to exclusive and inclusive values of V_{ub} . Therefore, it seems that refinements in the evaluation of exclusive and inclusive values of V_{ub} would have implications for the hierarchy of the elements of the texture 4 zero mass matrices.

As mentioned earlier, it seems interesting to compare the ranges of the elements of the above mentioned mass matrices with those constructed by Xing and Zhang [14]. The comparison immediately reveals that in the present work we have been able to achieve agreement with the CKM mixing data for much wider ranges of the elements of the mass matrices. A closer scrutiny of our results reveals that these wider ranges are essentially due to wider ranges for the hierarchy defining parameters D_U and D_D . It may be added that in case we restrict ourselves to the strong hierarchy case, then we are able to reproduce the matrices given by [14].

After constructing the mass matrices, it is desirable to construct the corresponding CKM mixing matrix and compare it with the one arrived through global analysis. To this end, we have considered the average value of V_{ub} given by PDG 2008, the other input parameters remain the same. The CKM mixing matrix so obtained is as follows

$$V_{\text{CKM}} = \begin{pmatrix} 0.9738 - 0.9747 & 0.2236 - 0.2274 & 0.00357 - 0.00429 \\ 0.2234 - 0.2274 & 0.9729 - 0.9739 & 0.0401 - 0.0423 \\ 0.0057 - 0.0114 & 0.0388 - 0.0420 & 0.9991 - 0.9992 \end{pmatrix}. \quad (20)$$

A general look at the matrix reveals that the ranges of CKM elements obtained here are quite compatible with those obtained by recent global analyses [15]- [18]. We have also evaluated the Jarlskog's rephasing invariant parameter J using the average value of V_{ub}

which comes out to be

$$J = (1.807 - 3.977)10^{-5}. \quad (21)$$

Further, using this value of J we obtain the following range of the CP violating phase δ

$$\delta = 28.8.8^\circ - 110.4^\circ. \quad (22)$$

The above mentioned ranges of the parameter J and the phase δ are inclusive of the values given by PDG 2008 [15].

5 Summary and conclusions

In the light of recent precision measurements, we have made an attempt to update and broaden the scope of the analysis carried out by Xing and Zhang [14] as well as have carried out a detailed analysis regarding the structural features of the mass matrices. The implications of these measurements on the texture 4 zero mass matrices have been examined by considering not only the usual ‘strong hierarchy’ amongst the elements of these matrices, defined as $D_i < |B_i| < C_i$, but also for the ‘weak hierarchy’ case given by $D_i \lesssim |B_i| \lesssim C_i$. For both the exclusive and inclusive values of V_{ub} , the analysis has been carried out by giving wide variation to the hierarchy defining parameters D_U and D_D . Further, in view of the more precise information regarding CP violating parameters, the ranges of both the phases ϕ_1 and ϕ_2 , having their origin in the mass matrices, have been found.

We find that despite considering weak hierarchy still both the phases are required to fit the data, in particular these come out to be $\phi_1 \sim 76^\circ - 92^\circ$ and $\phi_2 \sim 1^\circ - 11^\circ$. Also for both the exclusive and inclusive values of V_{ub} , the texture 4 zero mass matrices are compatible with recent results emerging from global fits [15]- [18] for weak as well as strong hierarchy of the elements of the mass matrices. A comparison of M_U^r and M_D^r matrices corresponding to exclusive and inclusive values of V_{ub} reveals that the parameters D_i and B_i ($i = U, D$) would have implications for these values of V_{ub} . In conclusion, we would like to state that even weakly hierarchical mass matrices can explain the quark masses and mixing data which are strongly hierarchical. This, in turn, would have important implications for model building of the fermion mass matrices.

Acknowledgements

RV would like to thank the Director, RIEIT for supporting the work. GA acknowledges DST, Government of India for financial support and the Chairman, Department of Physics for providing facilities to work. NM and MR would respectively like to thank the Chairman, Department of Physics and the Director, UIET for providing required facilities.
